

AI Tools

Currently I find myself in a mentorship program of web development, this involves learning some UI technologies, even though I think that the quality of what I could produce could barely reach a UI junior developer because I am not familiarized with some concepts of UI and UX, I would need to study furthermore about those areas so that I could feel confident on creating UI.

When it comes to producing using an AI tool I always restrain to ask the AI to produce routinary work, like an algorithm that I could search in google or information about a programming language, however, I once asked an AI tool to produce an interface for a JAVA program, the code was working but not exactly what I expected and that could be because of the prompt that I used when asking the code. Even if the code generated was matching with the prompt lacked some elements like the color palette or some text was not aligned. Still the result was useful and helped me with my assignment, I think this could be the same in a future with the UX role, where the designer can just focus on generating new ideas and the implementation is left to the AI tool, I think there is left a lot of travel for AI tools to generate UI with an specific look and feel with just a prompt.
